

OUR SOLAR SYSTEM

What's in Our Solar System?

The solar system is the group of objects that orbit around the Sun. Let's look at the objects that's inside the solar system.

The Sun

The sun is the star in the center of our solar system. Its gravity holds the objects in the system together.

Asteroids

Asteroids are rocky, metallic objects. Our solar system has an asteroid belt between Mars and Jupiter.

Comets

These are small and irregularly shaped objects made of ice. The heat of the ice vaporizes and leaves a tail behind when it comes closer to the Sun.

Moons

An object that orbits a planet. The earth has 1 moon, Mars has 2, while Jupiter has 80 moons.

Planets

The planets in the solar system are Mercury, Venus, Earth, Mars, Jupiter, Saturn, Uranus, and Neptune.

There are also dwarf planets. The five best-known dwarf planets are Ceres, Pluto, Makemake, Haumea, and Eris.

Sun

The Sun is a star, and it is the center of our solar system. It is an enormous, hot ball of gas, primarily hydrogen and helium, undergoing nuclear fusion in its core, which produces an immense amount of energy in the form of light and heat.

Mercury

Mercury is the smallest and innermost planet in our solar system, orbiting the Sun.

It is a rocky planet and has a surface that is covered in craters and looks somewhat like Earth's Moon.

Mercury experiences extreme temperatures, with scorching hot conditions on its sunlit side and extremely cold temperatures on its dark side.

Venus

Venus is the second planet from the Sun in our solar system, and it is often referred to as Earth's "sister planet" due to its similar size and composition.

Venus is the hottest planet in our solar system.

Venus is often visible from Earth and is one of the brightest objects in the night sky. It is sometimes referred to as the "Evening Star" or the "Morning Star," depending on its position relative to the Sun.

Earth

Earth is the third planet from the Sun in our solar system and is the only known celestial body to support life. Earth is the only known planet to support a wide variety of life forms. It includes diverse ecosystems ranging from microscopic organisms to complex plants and animals. Earth orbits the Sun, completing one orbit approximately every 365.25 days. This defines the length of a year.

Mars

Mars is the fourth planet from the Sun in our solar system and is often referred to as the "Red Planet" due to its reddish appearance. The surface of Mars also contains iron oxide, giving it a reddish color. This iron oxide, or rust, is responsible for the planet's distinctive appearance.

Jupiter

Jupiter is the fifth planet from the Sun in our solar system and is the largest planet, often referred to as a gas giant. Jupiter has a thick atmosphere with bands of clouds and storms. The most prominent feature is the Great Red Spot, a massive storm that has been raging for centuries.

Saturn

Saturn is the sixth planet from the Sun in our solar system, known for its stunning ring system. It is a gas giant mainly composed of gases

Uranus

Uranus is the seventh planet from the Sun in our solar system. It is a gas giant, often referred to as an "ice giant" due to its composition. It spins sideways unlike other planets

Neptune

Neptune is the eighth and farthest known planet from the Sun in our solar system. It is a gas giant, similar to Uranus, and is often referred to as an "ice giant" due to its composition and is one of the coldest planet

The Planets

Mercury is the closest planet to the Sun and has a rocky surface. It's very hot during the day and extremely cold at night.

Venus is similar in size to Earth and has a thick, poisonous atmosphere. It's known as Earth's "sister planet."

Earth is our home! It's the only planet we know of with life. It has a diverse climate, landforms, and oceans.

Mars is often called the "Red Planet" due to its rusty color. It has the largest volcano and canyon in the solar system.

Jupiter is the largest planet and a gas giant. It has a giant red spot, which is a massive storm.

Saturn is famous for its stunning ring system. It's another gas giant with beautiful rings made of ice and rocks.

Uranus is a unique planet because it rotates on its side. It's an ice giant and has a bluish-green color.

Neptune is the farthest planet from the Sun and is also an ice giant. It has strong winds and a dark spot similar to Jupiter's.

Moon

Moons are natural satellites that orbit planets. They are celestial bodies that are in orbit around a larger object, typically a planet, and they are a common feature in our solar system. Moons can vary greatly in size, composition, and characteristics.

1. Mercury: 0 moons
2. Venus: 0 moons
3. Earth: 1 moon (named "Moon")
4. Mars: 2 moons (Phobos and Deimos)
5. Jupiter: 80 known moons
6. Saturn: 83 known moons
7. Uranus: 27 known moons
8. Neptune: 14 known moons

Comets

Comets are small celestial bodies composed mostly of ice, dust, and volatile compounds, such as carbon dioxide, methane, ammonia, and water. These objects originate from the outer regions of the solar system, specifically from the Kuiper Belt and the Oort Cloud, which are regions of icy bodies beyond the orbit of Neptune.

Asteroid

Asteroids are small, rocky objects that orbit the Sun, primarily found in the inner solar system between the orbits of Mars and Jupiter. They are remnants from the early formation of the solar system and are composed of various minerals, metals, and other rocky materials.

Dwarf Planets

Dwarf planets are smaller than planets and may share orbits with other objects. Pluto, Eris, Haumea, Makemake, and Ceres are recognized as dwarf planets in our solar system. Dwarf planets are a category of celestial bodies that share similarities with planets but do not fulfill all the criteria to be classified as full-fledged planets.
